

4th Newsletter, December 2014

Dear reader,

Before you is the fourth edition of the IMPACTS newsletter, covering the period August – December 2014. The newsletters inform partners and stakeholders on the developments in the EU FP7 IMPACTS project¹. You can navigate through this document by clicking on the elements of the content list (below).

Previous newsletters:

About IMPACTS

IMPACTS is a collaborative project co-funded by the European Commission under the 7th Framework Programme. The goal of the IMPACTS project is to close knowledge gaps related to transport and storage of CO₂-rich mixtures from various CO₂ sources to enable realisation of safer and more cost-efficient solutions for CCS. The results of IMPACTS will help to ensure safe and reliable design, construction and operation of CO₂ pipelines and injection equipment, and safe long-term geological storage of CO₂. The project started on 1 January 2013 and has a duration of three years. It has 12 research performing partners and 5 funding partners. You can find more information on the project [website](#).

¹ If you wish to receive this newsletter, but are not on the mailing list, please send an e-mail to an.hilmo@sintef.no.

Events & meetings

Papers presented at the Greenhouse Gas Technologies conference 12 (GHGT12), October 6-9, 2014, Austin, Texas.

Two papers from the IMPACTS project were presented at the GHGT12 conference in Austin, Texas.

Stakeholder meeting, October 7, 2014, at the GHGT12 conference, Austin, Texas

An IMPACTS informational workshop was held during the GHGT 12 meeting in Austin on October 7th, 2014. Marit Mazzetti gave an overview presentation of IMPACTS. Marie Bysveen also from SINTEF gave an overview of the EERA CCS project. Then all the work packages gave a presentation. Jacob Stang from SINTEF represented WP1 talking about impact of impurities in CO₂ transport. And Sebastian Fischer from GFZ showed results from the important CO₂/N₂ injection experiments at Ketzin.

IMPACTS GOAL: *To develop the CO₂ quality knowledge base required for defining norms and regulations to ensure safe and reliable design, construction and operation of CO₂ pipelines and injection equipment, and safe long-term geological storage of CO₂*

Filip Neele presented the work to be performed in WP3 as that has just now started. There was great interest in the techno economic assessment and the tools that are under development in WP3. The techno-economic tool aims to study the relation between CO₂ quality and the cost of constructing and operating a CCS system (including capture, transport and storage).

There was also an interesting guest lecture by Rebecca Hollins from CO₂ Global, USA. As Texas has the longest experience with operating CO₂ pipelines in the world, it was interesting to learn from the US Experience of impact of impurities in CO₂ pipelines.

IMPACTS Information workshop, GHGT12

The US has an extensive network of CO₂ pipelines as can be seen from the picture from Dr. Hollis's presentation shown below. The US pipelines are regulated by the US Department of Transportation.

IMPACTS

The impact of the quality of CO₂ on transport and storage behaviour

The CO₂ pipelines are not hazardous. A 90% molar purity is required for supercritical. Pressure rating is 2-3000 psig, about 3 times that of natural gas pipelines.

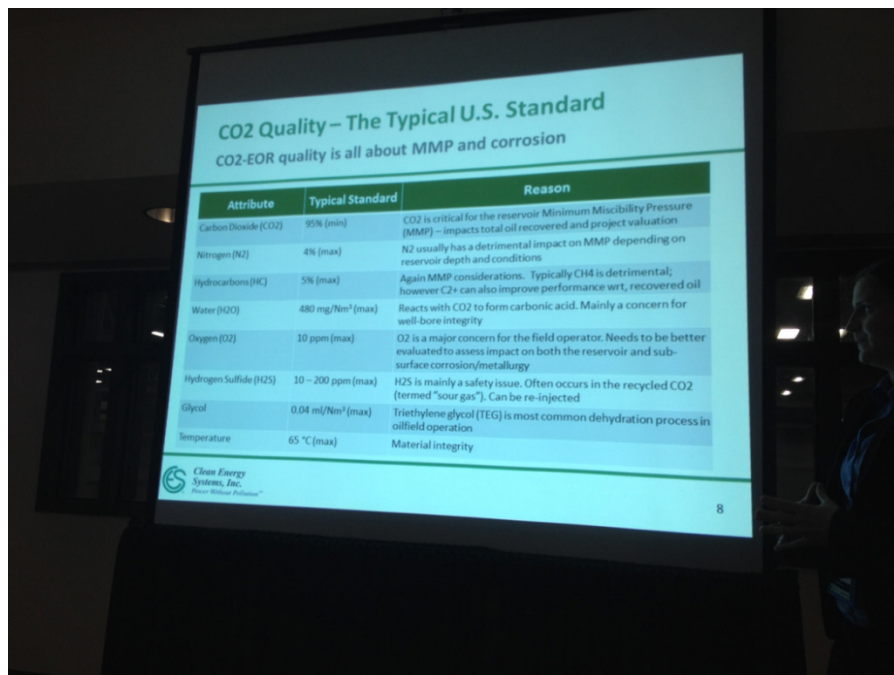

The standard in the US has been CO₂ for use in EOR. The CO₂ quality is therefore all about corrosion and MMP (Minimum Miscibility Pressure) which impacts total oil recovered and project valuation. The CO₂ is set to 95% purity. The nitrogen is limited to 4 % as it usually has a detrimental impact on MMP depending on reservoir depth and conditions.

Oxygen is set at 10 ppm max. It is a major concern for the field operator. It needs to be better evaluated to assess impact on both the reservoir and sub-surface corrosion/metallurgy. There is a H₂S requirement set at 10-200ppm (max.). It is a safety issue. It can be re-injected however.

Points brought up for further consideration were:

- There is extensive experience with CO₂ for EOR, however there is little compatibility with this and the requirements for storage in Deep Saline Formations (DSF).
 - DSF is more related to criteria for environment and safe drinking water
- There also remain challenges for defining CO₂ quality criteria with various capture technologies that require different downstream CO₂ processing and clean-up.

Overall it was an interesting workshop with great interaction and discussions among the participants.

Summary of the US Standard for CO₂ Quality by Rebecca Hollins, Clean Energy Systems, USA

Impacts Informational Workshop Programme

14:15-14:30: Welcome and Introduction to the IMPACTS project

Marit Mazzetti, SINTEF

14:30-14:40: The EERA CCS project

Marie Bysveen, SINTEF

14:40-15:00: EOR requirements for CO₂ quality and composition- Experience from US Projects

Rebecca Hollis, Clean Energy Systems

15:00-15:15: Impact of impurities on CO₂ transport

Jacob Stang, SINTEF

15:15-15:30: Results from CO₂/N₂ injection experiment

Sebastian Fischer, GFZ

15:30-15:45 Techno-economic evaluation in Impacts

Filip Neele, TNO

15:45-15:55: Discussion and Wrap-Up

Workshop on September 23-24, at TNO, Utrecht, The Netherlands

Following the workshop in June, 2014, also held at TNO in The Netherlands, a second workshop was organised to further discuss the translation of results from the work done in the 'technical work packages' to input for the techno-economic model of CCS chains. The technical work packages focus on the study of CO₂ mixtures in such areas as fluid properties and behaviour, corrosion and transport and injection. In IMPACTS, the results from these studies are to be used to reach conclusions about the relation between the quality of the CO₂ stream and the design and operation of CCS chains –in terms of safety, technology and economics. The project's goal is a series of studies of the trade-offs between mixture quality and the costs of building and operating a CCS chain in various different circumstances.

The workshop concluded with identifying how each of the main categories of expected impurity influences were going to be "translated", what kind of result could be anticipated in each case and (importantly) who was going to provide what. This information is held in a document commonly known as the SP2 Shopping List.

Executive Board meeting, October 20, 2014, Ruhr Universität Bochum, Germany

The third EB meeting was held in October, in Bochum, hosted by the Ruhr Universität in Bochum.

Consortium technical meeting, October 21, 2014, Ruhr Universität Bochum, Germany

A technical meeting was held on the day following the Executive Board meeting. The meeting was attended by most IMPACTS participants and used to update the group on the progress of work in the

various work packages, as well as to look ahead at 2015, the final year of the project, and to prepare for dissemination activities like conference attendance and workshops.

After the meeting the lab facilities of the research group of Prof. Span were visited, to view the installations used to measure gas mixture properties.

A gas mixing installation in the labs of Ruhr University

Current activities

WP1.2 Thermophysical behaviour of CO₂ mixtures

In September 2014 Ruhr-University Bochum in Denmark organized an international workshop addressing algorithms for the evaluation of multiparameter mixture models. 22 scientists from six countries (including the USA and Japan) joined the workshop, which was closely related to the goals addressed in WP1.2 in Impacts. The whole team working on thermodynamic property models in IMPACTS attended the workshop.

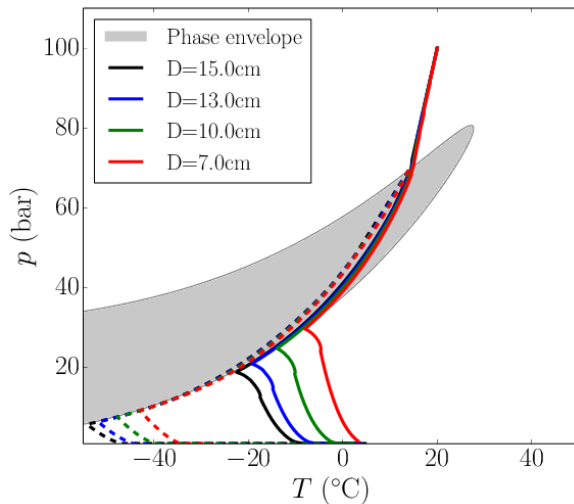

Participants of the modelling workshop in Denmark

Results of the work in Impacts were presented on the workshop “CO₂ Properties and EoS for Pipeline Engineering” organized by the UKCCS Research Centre in York in November.

The experimental work at Tsinghua and Ruhr-Universität continues. The data generated at both laboratories are directly utilized in the development of improved property models. Mutual visits have strengthened the cooperation between both groups. From October 2014 to March 2015 Xiaoxian Yang, a young researcher working on the Impacts project at Tsinghua University, stays at Ruhr-University as guest researcher to further intensify the cooperation.

WP1.3 Transient fluid dynamics of CO₂ mixtures

WP1.3 produced two deliverables in the past six months. The first concerned the effect of impurities on the lowest temperature reached during a depressurization. When emptying a pipeline filled with CO₂ there will be a large cooling due to the evaporation of the initially liquid CO₂. The report shows that the studied impurities (N₂, O₂, H₂, CH₄, C₂H₆) have a positive effect on the lowest temperature, that is there is less cooling than with pure CO₂. It also points out that the area of the valve through which the pipe is emptied has a much larger effect than impurities, as shown in the figure below.

Results from the de-pressurisation of a pipeline containing CO₂ with 5 mol% N₂, with varying valve opening diameter. The plot shows the state close to the valve (solid line) and at the escape-point inside the valve (dashed line), on top of the phase envelope for the initial mixture.

The second report contains a benchmark of three different simulation tools for CO₂ pipeline: The commercial simulator OLGA, ANSYS Fluent with CSM's thermodynamic library CO₂ GASMISC, and SINTEF Energy Research' in-house code. Both steady-state flow and depressurization and filling of a pipeline were considered, with impurities typical for various capture processes. Especially for depressurization and filling some discrepancies were found between the various tools. The report shows that simulation of two-phase flow of CO₂ with impurities still requires more research.

WP1.4 Corrosion potentials in CO₂ infrastructure

Corrosion and test corrosion tests are ongoing. Three different pipeline materials have been selected for the testing activity:

- Grade X60
- Grade X65
- Grade X70

The test corrosion testing activity will include measurements on samples cut out from a girth weld. All the samples have been machined. All the testing activity will finish in the first months of 2015.

WP1.5 Chemical and physical effects of impurities on CO₂ storage

Within the last months the work performed in WP1.5 made a great step forward towards understanding the physicochemical effects of an impure CO₂ stream in the deep subsurface during injection and subsequent storage. Reservoir engineering simulations were conducted, considering mixture of gases, like CO₂ and SO₂, and assessed the influence of the various impurity concentrations in the CO₂ stream on e.g. the pressure development and storage capacity. In addition, the presence of CO₂ and additional substances has varying influences on chemical fluid-rock interactions and results most notably in dissolution of primary minerals and the precipitation of newly formed phases, causing changes in porosity and permeability. By using geochemical modelling tools we showed that the presence of SO₂ may have a significant influence on the porosity evolution of the

reservoir sandstones over time. The fluid-rock interactions also caused minor pressure changes due to the transition of the gas-fluid-solid phases. In a second step, the porosity and pressure changes were integrated in an updated reservoir model to assess the influence of chemical mineral reactions on e.g. storage capacity. Although the chemical reactivity plays a role in geochemical models, the corresponding influence on the storage capacity was found to be insignificant. Similar geochemical modelling approaches and corresponding sensitivity analyses were performed on caprock material.

WP2.1 Operational and material effects of impurities in CO₂ streams

During the last quarter of 2014 CIUDEN has conducted internal tests to prepare in advance the CO₂ transport installation for measurements to be done early 2015. In parallel, a draft test matrix has been presented to the partners in Bochum for discussion; inputs and support were received from the group. CIUDEN is working jointly with PEL in the preparation of a special sample to be installed during the test session.

CO₂ back-production at the Ketzin pilot site successfully performed

To study the geochemical and operational effects of impure CO₂ and its subsurface behaviour, a four week N₂-CO₂ co-injection field test was conducted at the Ketzin pilot site in summer 2013 (see IMPACTS Newsletter No. 2). Major objectives included demonstrate the technical feasibility of a continuous N₂-CO₂ co-injection scenario, monitor spreading and behaviour of the CO₂-N₂ gas mixture in the reservoir, and determine potential chromatographic effects within the reservoir. During the field test, a total of 32 t of N₂ and 613 t of CO₂ were co-injected to ensure a CO₂:N₂ ratio of approximately 95:5. The CO₂-N₂ co-injection was followed by a final injection of 66 t pure CO₂. To allow study isotopic mixing effects, CO₂ from a natural CO₂ source was used for the field test instead of the normally used industrial CO₂ from a refinery process. The natural CO₂ had a much heavier carbon isotope composition ($\delta^{13}\text{C} = -3.4 \pm 0.2\text{‰}$) than the industrial CO₂ ($\delta^{13}\text{C} = -30.6 \pm 0.4\text{‰}$). To chemically mark the start of N₂-CO₂ co-injection field test, Krypton and SF₆ as additional inert tracers were injected. A capillary riser tube installed in a nearby observation well at 25 m distance to the injection well was used to collect reservoir fluid and gas samples. Based on Kr and $\delta^{13}\text{C}$ data, the CO₂-N₂ gas mixture arrived after about 17 days at the observation well. Increasing Kr concentrations positively correlate with both increasing N₂ concentrations and $\delta^{13}\text{C}$ values. Additionally, the $\delta^{13}\text{C}$ data also indicate mixing between natural and industrial CO₂ within the reservoir. The N₂-CO₂ co-injection field test terminated the injection period at the Ketzin site.

Picture courtesy T. Kollersberger, GFZ German Research Centre for Geosciences

The field test on N₂-CO₂ co-injection was complemented in October 2014 - 14 months after end of injection - by a field experiment on the back production of the formerly injected CO₂-N₂ stream from the reservoir. The field experiment aimed at three main questions: What is the chemical composition of the back produced CO₂ and the co-produced formation fluid? What is the behaviour of the reservoir and the wellbore during back production of CO₂? What is the surface spreading of the back produced CO₂? Over 13 days 240 t of CO₂ and 57 m³ formation fluid have been safely and smoothly back produced from the reservoir and continuously sampled and analysed. The measured compositions of back produced CO₂ and formation fluid will allow study the geochemical interactions between impure CO₂, formation fluid and rocks under real in-situ conditions. First results indicate that the back produced CO₂ has a purity > 97%. Most important impurity in the back-produced CO₂ stream is N₂ which most probably stems from the N₂-CO₂ co-injection experiment. The N₂ concentration in the CO₂ stream decreased from about 3% to 1% during the two weeks duration of the experiment. During the back-production experiment, the N₂ was detected ab initio, although the N₂-CO₂ co-injection terminated with pure CO₂. Besides N₂, also the tracers Kr and SF₆ from the N₂-CO₂ co-injection experiment were detected with low concentrations of < 0.001%. First data on the composition of the back produced reservoir fluid suggest slightly increased potassium, magnesium and iron concentrations compared to pre-injection baseline data.

For more information about the Ketzin project, see the project [web site](#).

WP2.2 Techno-economic analyses of impacts of CO₂ quality

The main activity within this work package has been to develop the ways in which the chemical and physical effects of impurities in the CO₂ stream, derived from other work packages can be represented as cost influences within the techno-economic modelling work. This has been discussed carefully at the workshops in Utrecht (see above) and the model is being prepared to accept the expected results.

Another focus is improving the CCS chain cost database for the modelling work; this is being derived from both public and partner information and will be used to populate the basic economic model and the detailed cost influences.

WP2.3 Risk assessment

August 2014, WP2.3 participants delivered a comprehensive report, mapping the state-of-the-art in CCS risk assessment, existing recommended practices, guidelines and software. Considering the IMPACTS project scope, particular focus is placed on CO₂ with impurities. See below, report D2.3.1 under [Publications](#), for a brief summary.

In 2015 work will be carried out to improve modelling of a worst case accidental release scenario, for instance a transport pipeline failure. The common practice with respect to quantitative risk assessment will be fine-tuned, will focus on the influence of impurities on CO₂ release behaviour. Thereto IMPACTS project aims for available datasets (release experiments of pure CO₂, not performed within the IMPACTS project), and make use of the equations of state produced by Ruhr Universität Bochum.

WP3.1 IMPACTS recommendations

This work packages, which started in the second half of 2014, aims to combine all results in IMPACTS into a set of recommendations for CCS projects. The recommendations will summarise the impact of the CO₂ composition, or of changing composition, on the design, operation and performance of CCS chains.

The recommendations will be presented in an IMPACTS report.

In 2014 the definition of the framework for the recommendations has started.

WP3.2 IMPACTS Toolbox

One of the deliverables from IMPACTS will be a 'Toolbox', which will contain all relevant results, conclusions, guidelines, rules of thumb, etc. from the various work packages in the project. Together with the recommendations from the overall project, which will be defined in WP3.1, this Toolbox aims to provide the data and results that can be used by CCS projects to establish the impact of impurities on their intended or ongoing project.

One element of the Toolbox is a new CO₂ properties reference model, which will contain all results obtained by Ruhr Universität Bochum, on the physical properties of CO₂ mixtures.

The work in the part of the project started in the second half of 2014, with a preliminary inventory of potential elements of the Toolbox.

WP3.3 Dissemination plan and IMPACTS workshop

This work packages contains the key dissemination activities in IMPACTS in 2015. These include:

- A workshop at the TCCS-8 conference in Trondheim, in June 2015. Prior to the conference, a workshop for stakeholders will be organised, to present the results obtained until that time (including the Toolbox, see WP3.2) and to discuss the framework for the formulation of recommendations (see WP3.1).
- A CCS course will be organised in Rumania in the Fall of 2015. Adjusted to the Master student level, the course will be open to both academia and people from industry. IMPACTS researchers will give lectures at the course.

These activities form the first steps towards the definition of the IMPACTS results exploitation plan, which will be set up in this work package.

IMPACTS

The impact of the quality of CO₂ on transport and storage behaviour

Publications

In the past period the following deliverables were produced.

Poster at GHGT12 conference (October 2014, Austin TX), IMPACTS: economic trade-offs for CO₂ impurity specification by Charles Eickhoff (PEL), Filip Neele (TNO), Morten Hammer (SINTEF), Massimo DiBiagio (CSM), Cor Hofstee (TNO), Marielle Koenen (TNO), Sebastian Fischer (GFZ), Anastasia Isaenko (DNV-GL), Andy Brown (PEL), Timea Kovacs (CIUDEN)

The poster gives an overview of the IMPACTS project, with a focus on the techno-economic analysis that aims to analyse the trade-off between efforts at the capture side to deliver pure CO₂ and investments in transport and storage to deal with CO₂ with impurities.

 Coordinator: SINTEF ER (Norway)

Introduction

The IMPACTS project (2013-2016) has the objective to develop the knowledge base of CO₂ quality required for establishing norms and regulations to ensure safe and reliable design, construction and operation of CO₂ pipelines and injection equipment, and safe long-term geological storage of CO₂.
 More specifically, the project aims to reveal the impacts of relevant impurities in the CO₂ stream on the design, operation and costs of the capture, transport and storage infrastructure and to provide recommendations for optimized CO₂ quality through techno-economic assessments.

The first step in the project was to assemble a list of expected CO₂ stream compositions from typical CO₂ source and capture technology combinations. These compositions are used in IMPACTS as reference mixtures in a series of 'reference CCS chains'.
 Concentrations in ppmv (unless marked as %).

CO ₂ source	CO ₂ capture technology	CO ₂ concentration (ppmv)	CO ₂ purity (%)	CO ₂ flow (t/h)	CO ₂ pressure (bar)	CO ₂ temperature (°C)	CO ₂ viscosity (mPa·s)	CO ₂ density (kg/m ³)	CO ₂ speed of sound (m/s)	CO ₂ thermal conductivity (W/m·K)	CO ₂ specific heat capacity (kJ/kg·K)	CO ₂ latent heat of vaporization (kJ/kg)	CO ₂ critical temperature (°C)	CO ₂ critical pressure (bar)	CO ₂ critical density (kg/m ³)
CO ₂	99%	99%	99%	95%	95%	95%	97%								
N ₂	2000	2000	2000	6000	2.5%	5000	30								
O ₂	200	200	1	1.6%			5								
Ar	100	100	500	6000											
NO _x	50	50	100												
SO _x	10	10	100												
CO	10	10	400	50

H ₂			1%												
CH ₄			1000												
C ₂ +															
NH ₃	1	100													
Amine	1														

Toolbox

The results from the IMPACTS project will be delivered in the form of a Toolbox, that contains not only the results from detailed analyses of the effects of mixture composition on aspects or chain design and operation versus CO₂ quality.

Examples of physical effects of impurities in different parts of the CCS chain and their impact on aspects of the CCS chain

CCS chain aspect affected	Fundamental data needed	Local Processing needed	Impact on CCS techno-economic model aspect
Permeability effects	Changes to near-permeability / porosity due to impurity levels / combinations	Changes to near-permeability / porosity due to chemical interactions	Flow rate / capacity / pressure impacts
Precipitation of minerals in storage	Chemical precipitation at various formation and fluid combinations with impurity levels	Blockage effects on CO ₂ flow in formation	Flow rate / capacity / pressure impacts
Caprock stability	Deterioration of caprock integrity due to chemical effects of impurities	Impact of any caprock interactions affecting integrity at impurity levels	Limits or additional costs to caprock integrity / impurity combinations; additional monitoring costs
Biological impact	Growth of SRBs and other algae etc. at various impurity levels	Shading and storage effects and resulting impacts	Impurity related costs to caprock integrity / impurity combinations
Wellbore cement corrosion	Chemical impacts on wellbore cements due to impurity levels / combinations	Changes to permeability / porosity due to chemical interactions	Limits or additional costs to wellbore integrity / impurity combinations
Injection rates	Phase behaviour, viscosity of mixtures	Equations of state for various mixtures	Impact on well head pressure
Reservoir capacity	Density, pressure of mixtures in reservoir	Equations of state for various mixtures	Impact on storage capacity
Pressure drop during transport	Phase behaviour, viscosity of mixtures	Equations of state for various mixtures	Impact on required compressor capacity
Behaviour of mixture during transport	Density, pressure of mixtures in reservoir	Equations of state for various mixtures	Requirements on safe operating regime
Corrosion of pipelines	Effects H ₂ O, SO ₂ , H ₂ S in CO ₂ results on corrosion rates	Corrosion and stress corrosion tests	Material quality requirements
Seismic safety	E.g. reactivity and concentrations of sulphates	E.g. dispersion of CO ₂ mixture	Design requirements, e.g. pipeline wall thickness

ACKNOWLEDGEMENTS

The research leading to these results received funding from the European Union Seventh Framework Programme (FP7/2007-2013) under grant agreement n° 308800.

Poster at GHGT12 conference (October 2014, Austin TX), N₂-CO₂ co-injection field test at the Ketzin pilot CO₂ storage site by Sebastian Fischer (GFZ)

This poster presented the injection of CO₂ and N₂ at the Ketzin site in Germany, also described above.

Keynote lecture, *Thermodynamic Property Models for Transport and Storage of CO₂* - Roland Span, Ruhr-Universität Bochum, Germany, Presented at CO₂ Properties and EoS for Pipeline Engineering, 11th November 2014

Roland Span presented on property model of CO₂ mixtures. [More...](#)

D1.3.1 Report assessing the influence of CO₂ mixture composition in relevant cases, using preliminary model by Eskil Aursand (SINTEF)

This work is a computational study of the depressurisation of high-pressure pipelines containing CO₂ with the major (>1%) impurities expected from typical carbon capture technologies (N₂, O₂, H₂, CH₄ and C₂H₆). The focus was the effects these impurities may have on the temperature drop occurring close to and within the depressurization valve, as low temperatures could pose a safety hazard. [More...](#)

D1.3.4 Benchmark study including commercially available tools and the model developed in Task 1.3.1. by Jérémy Veltin (TNO), Halvor Lund (SINTEF) and Marco Bertoli (CSM)

Simulation of pipe flows with CO₂ and CO₂ mixtures is not yet current practice. A number of codes originally developed for the oil and gas industry can be used for this purpose. This report presents a comparison between different codes. Especially when phase change is expected, large deviations can be seen between codes. However such operational conditions are unlikely to occur very often during the lifetime of a pipeline. [More...](#)

D2.3.1 Existing practice in risk assessment for CCS by Angun Engebo (DNV-GL), Anastasia Isaenko (DNV-GL), Mark Spruijt (TNO), Ingrid Raben (TNO), Andy Brown (PEL)

There is an urgent drive to implement Carbon Capture and Storage (CCS) on a commercial and global scale. For success this needs to be done in a demonstrably safe and responsible manner that gains widespread acceptance of stakeholders, most notably regulators and the public. The goal of this report is to map state-of-the-art in CCS risk assessment, existing recommended practices, guidelines and software. Particular focus is placed on CO₂ with impurities. [More...](#)
